

Height

- The running time of the search an insertion algorithms is affected by the height h of the skip list
- We show that with high probability, a skip list with n items has height O(log n)
- We use the following additional probabilistic fact:
 - Fact 3: If each of *n* events has probability *p*, the probability that at least one event occurs is at most *np*

- Consider a skip list with n entires
 - By Fact 1, we insert an entry in list *S_i* with probability 1/2ⁱ
 - By Fact 3, the probability that list S_i has at least one item is at most $n/2^i$
- □ By picking $i = 3\log n$, we have that the probability that $S_{3\log n}$ has at least one entry is at most

$$n/2^{3\log n} = n/n^3 = 1/n^2$$

Thus a skip list with n entries has height at most $3\log n$ with probability at least $1 - 1/n^2$

Search and Update Times

- The search time in a skip list is proportional to
 - the number of drop-down steps, plus
 - the number of scan-forward steps
- The drop-down steps are bounded by the height of the skip list and thus are O(log n) with high probability
- To analyze the scan-forward steps, we use yet another probabilistic fact:

Fact 4: The expected number of coin tosses required in order to get tails is 2

- When we scan forward in a list, the destination key does not belong to a higher list
 - A scan-forward step is associated with a former coin toss that gave tails
- By Fact 4, in each list the expected number of scanforward steps is 2
- \Box Thus, the expected number of scan-forward steps is $O(\log n)$
- We conclude that a search in a skip list takes O(log n) expected time
- The analysis of insertion and deletion gives similar results
