## Pattern Matching

## Strings (§ 11.1)

- A string is a sequence of characters
- Examples of strings:
- Java program
- HTML document
- DNA sequence
- Digitized image
- An alphabet $\Sigma$ is the set of possible characters for a family of strings
- Example of alphabets:
- ASCII
- Unicode
- $\{0,1\}$
- $\{\mathrm{A}, \mathrm{C}, \mathrm{G}, \mathrm{T}\}$
© 2004 Goodrich, Tamassia
- Let $\boldsymbol{P}$ be a string of size $\boldsymbol{m}$
- A substring $P[i . . j]$ of $P$ is the subsequence of $P$ consisting of the characters with ranks between $i$ and $j$
- A prefix of $P$ is a substring of the type $P[0$.. $i]$
- A suffix of $P$ is a substring of the type $P[\boldsymbol{i} . . \boldsymbol{m}-1]$
* Given strings $T$ (text) and $P$ (pattern), the pattern matching problem consists of finding a substring of $T$ equal to $P$
- Applications:
- Text editors
- Search engines - Biological research

## Brute-Force Pattern <br> Matching (§ 11.2.1)

- The brute-force pattern matching algorithm compares the pattern $P$ with the text $T$ for each possible shift of $\boldsymbol{P}$ relative to $T$, until either
- a match is found, or
- all placements of the pattern have been tried
- Brute-force pattern matching runs in time $\boldsymbol{O}(\boldsymbol{n m})$
- Example of worst case:
- $T=a a a \ldots a h$
- $P=a a a h$
- may occur in images and DNA sequences
- unlikely in English text

Algorithm BruteForceMatch(T, P)
Input text $\boldsymbol{T}$ of size $\boldsymbol{n}$ and pattern $\boldsymbol{P}$ of size $\boldsymbol{m}$
Output starting index of a substring of $\boldsymbol{T}$ equal to $\boldsymbol{P}$ or -1
if no such substring exists
for $i \leftarrow 0$ to $n-m$
\{ test shift $\boldsymbol{i}$ of the pattern \}
$j \leftarrow 0$
while $j<m \wedge T[i+j]=P[j]$
$j \leftarrow j+1$
if $\boldsymbol{j}=\boldsymbol{m}$
return $i$ \{match at $i\}$
else
break while loop \{mismatch\}
return -1 \{no match anywhere\}

## Boyer-Moore Heuristics (§ 11.2.2)

* The Boyer-Moore's pattern matching algorithm is based on two heuristics
Looking-glass heuristic: Compare $\boldsymbol{P}$ with a subsequence of $T$ moving backwards
Character-jump heuristic: When a mismatch occurs at $T[i]=c$
- If $P$ contains $c$, shift $P$ to align the last occurrence of $c$ in $P$ with $T i]$
- Else, shift $P$ to align $P[0]$ with $T[i+1]$
- Example

| $a$ | $p$ | $a$ | $t$ | $t$ | $e$ | $r$ | $n$ |  | $m$ | $a$ | $t$ | $c$ | $h$ | $i$ | $n$ | $g$ |  | $a$ | $l$ | $g$ | $o$ | $r$ | $i$ | $t$ | $h$ | $m$ |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- |

## Last-Occurrence Function

- Boyer-Moore's algorithm preprocesses the pattern $\boldsymbol{P}$ and the alphabet $\Sigma$ to build the last-occurrence function $L$ mapping $\Sigma$ to integers, where $L(c)$ is defined as
- the largest index $\boldsymbol{i}$ such that $P[i]=\boldsymbol{c}$ or
- -1 if no such index exists
- Example:
- $\Sigma=\{a, b, c, d\}$
- $P=a b a c a b$

| $\boldsymbol{c}$ | $\boldsymbol{a}$ | $\boldsymbol{b}$ | $\boldsymbol{c}$ | $\boldsymbol{d}$ |
| :---: | :---: | :---: | :---: | :---: |
| $\boldsymbol{L}(\boldsymbol{c})$ | 4 | 5 | 3 | -1 |

- The last-occurrence function can be represented by an array indexed by the numeric codes of the characters
- The last-occurrence function can be computed in time $\boldsymbol{O}(\boldsymbol{m}+\boldsymbol{s})$, where $\boldsymbol{m}$ is the size of $P$ and $s$ is the size of $\Sigma$

## The Boyer-Moore Algorithm

Algorithm BoyerMooreMatch $(T, P, \Sigma)$
$L \leftarrow$ lastOccurenceFunction $(P, \Sigma)$
$i \leftarrow m-1$
$j \leftarrow m-1$
repeat
if $T[i]=P[j]$
if $j=0$
return $\boldsymbol{i}$ \{ match at $\boldsymbol{i}$ \}
else
$i \leftarrow i-1$
$j \leftarrow j-1$
else
\{ character-jump \}
$l \leftarrow L[T i]]$
$\boldsymbol{i} \leftarrow \boldsymbol{i}+\boldsymbol{m}-\min (\boldsymbol{j}, 1+\boldsymbol{l})$
$j \leftarrow m-1$
until $i>n-1$
return -1 \{no match \}

Case 1: $\boldsymbol{j} \leq 1+\boldsymbol{l}$

Case 2: $1+\boldsymbol{l} \leq \boldsymbol{j}$

6

## Example

## Analysis

- Boyer-Moore's algorithm runs in time $\boldsymbol{O}(\boldsymbol{n m}+\boldsymbol{s})$
- Example of worst case:
- $T=a a a \ldots a$
- $P=b a a a$
- The worst case may occur in images and DNA sequences but is unlikely in English text
- Boyer-Moore's algorithm is significantly faster than the brute-force algorithm on English text

$$
\begin{array}{|c|l|l|l|l|l|}
6 & 5 & 4 & 3 & 2 & 1 \\
\hline b & \boldsymbol{a} & \boldsymbol{a} & \boldsymbol{a} & \boldsymbol{a} & \boldsymbol{a} \\
\hline
\end{array}
$$

$$
\begin{array}{|c|c|c|c|c|c|c|}
\hline 12 & 11 & 10 & 9 & 8 & 7 \\
\hline \boldsymbol{b} & \boldsymbol{a} & \boldsymbol{a} & \boldsymbol{a} & \boldsymbol{a} & \boldsymbol{a} \\
\hline
\end{array}
$$

$$
\begin{array}{llllllll}
18 & 17 & 16 & 15 & 14 & 13 \\
\hline \boldsymbol{b} & \boldsymbol{a} & \boldsymbol{a} & \boldsymbol{a} & \boldsymbol{a} & \\
\hline
\end{array}
$$

## The KMP Algorithm (§ 11.2.3)

- Knuth-Morris-Pratt's algorithm compares the pattern to the text in left-to-right, but shifts the pattern more intelligently than the brute-force algorithm.
- When a mismatch occurs, what is the most we can shift the pattern so as to avoid redundant comparisons?
- Answer: the largest prefix of $P[0 . . j]$ that is a suffix of $P[1 . j]$

## KMP Failure Function

- Knuth-Morris-Pratt's algorithm preprocesses the pattern to find matches of prefixes of the pattern with the pattern itself
- The failure function $F(j)$ is defined as the size of the largest prefix of $P[0 . . j]$ that is also a suffix of $P[1 . . j]$
- Knuth-Morris-Pratt's algorithm modifies the bruteforce algorithm so that if a mismatch occurs at $P[j] \neq \boldsymbol{T}[i]$

| $\boldsymbol{j}$ | 0 | 1 | 2 | 3 | 4 | 5 |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| $P[j]$ | $\boldsymbol{a}$ | $\boldsymbol{b}$ | $\boldsymbol{a}$ | $\boldsymbol{a}$ | $\boldsymbol{b}$ | $\boldsymbol{a}$ |
| $\boldsymbol{F}(\boldsymbol{j})$ | 0 | 0 | 1 | 1 | 2 | 3 |

## The KMP Algorithm

- The failure function can be represented by an array and can be computed in $\boldsymbol{O}(\boldsymbol{m})$ time
- At each iteration of the whileloop, either
- $i$ increases by one, or
- the shift amount $\boldsymbol{i}-\boldsymbol{j}$ increases by at least one (observe that $\boldsymbol{F}(\boldsymbol{j}-1)<\boldsymbol{j}$ )
- Hence, there are no more than $2 \boldsymbol{n}$ iterations of the while-loop
- Thus, KMP's algorithm runs in optimal time $\boldsymbol{O}(\boldsymbol{m}+\boldsymbol{n})$

```
Algorithm KMPMatch(T, P)
    F}\leftarrow\mathrm{ failureFunction(P)
    i}\leftarrow
    j}\leftarrow
    while i<n
        if T[i]=P[j]
            if }\boldsymbol{j}=\boldsymbol{m}-
            return i-j {match }
            else
                                i\leftarrowi+1
                j}\leftarrowj+
            else
            if }\boldsymbol{j}>
                    j}\leftarrowF[j-1
            else
                i}\leftarrowi+
    return -1 {no match}
```

## Computing the Failure Function

- The failure function can be represented by an array and can be computed in $\boldsymbol{O}(\boldsymbol{m})$ time
- The construction is similar to the KMP algorithm itself
- At each iteration of the whileloop, either
- $i$ increases by one, or
- the shift amount $\boldsymbol{i}-\boldsymbol{j}$ increases by at least one (observe that $\boldsymbol{F}(\boldsymbol{j}-1)<\boldsymbol{j}$ )
- Hence, there are no more than $2 \boldsymbol{m}$ iterations of the while-loop

Algorithm failureFunction( $P$ )
$F[0] \leftarrow 0$
$i \leftarrow 1$
$j \leftarrow 0$
while $i<m$
if $P[i]=P[j]$
\{we have matched $\boldsymbol{j}+1$ chars \}
$F[i] \leftarrow j+1$
$i \leftarrow i+1$
$j \leftarrow j+1$
else if $j>0$ then
\{use failure function to shift $\boldsymbol{P}$ \} $j \leftarrow F[j-1]$
else
$F[i] \leftarrow 0\{$ no match \}
$i \leftarrow i+1$

## Example

|  | a | $b$ | $a$ | $c$ | $a$ | $a$ |  | $b$ | $a$ | c | c | $a$ | $b$ |  | $a$ | $c$ |  | $a$ | $b$ |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  |  | 2 | 3 | 4 | 5 | 6 |  |  |  |  |  |  |  |  |  |  |  |  |  |
|  | $a$ | $b$ | $a$ | c | $a$ | $b$ |  |  |  |  |  |  |  |  |  |  |  |  |  |
|  |  |  |  |  |  | 7 |  |  |  |  |  |  |  |  |  |  |  |  |  |
|  |  |  |  |  | $a$ | $b$ |  | $a$ | $c$ | $a$ | $b$ |  |  |  |  |  |  |  |  |
|  |  |  |  |  |  |  |  | 9 | 10 | 11 | 12 |  |  |  |  |  |  |  |  |
|  |  |  |  |  |  | $a$ |  | $b$ | $a$ | $c$ | $a$ | $b$ |  |  |  |  |  |  |  |
|  |  |  |  |  |  |  |  |  |  |  | 13 |  |  |  |  |  |  |  |  |
|  |  |  |  |  |  |  |  |  |  |  | $a$ | $b$ | $a$ |  | $c$ | $a$ |  | $b$ |  |
| ${ }^{j}$ | 0 | 1 |  | 2 | 3 |  | 4 |  | 5 |  |  |  |  |  |  |  |  |  |  |
| $P[j]$ | $a$ | $b$ |  | $a$ | c |  | $a$ |  | $b$ |  |  |  |  |  |  |  |  |  |  |
| $F(j)$ | 0 | 0 |  | 1 | 0 |  | 1 |  | 2 |  |  |  |  |  |  |  |  |  |  |
