## $(2,4)$ Trees

$\qquad$
$\qquad$

## Multi-Way Inorder Traversal

- We can extend the notion of inorder traversal from binary trees to multi-way search trees
- Namely, we visit item $\left(\boldsymbol{k}_{i}, \boldsymbol{o}_{i}\right)$ of node $\boldsymbol{v}$ between the recursive traversals of the subtrees of $v$ rooted at children $v_{i}$ and $v_{i+1}$
- An inorder traversal of a multi-way search tree visits the keys in increasing order

## Multi-Way Search Tree (§ 9.4.1)

* A multi vay search tree is an ordered tree such that
- Each internal node has at least two children and stores $\boldsymbol{d}-1$ key-element items $\left(\boldsymbol{k}_{\boldsymbol{i}}, \boldsymbol{o}_{\boldsymbol{i}}\right)$, where $\boldsymbol{d}$ is the number of children
- For a node with children $\boldsymbol{v}_{1} \boldsymbol{v}_{2} \ldots \boldsymbol{v}_{d}$ storing keys $\boldsymbol{k}_{1} \boldsymbol{k}_{2} \ldots \boldsymbol{k}_{d-1}$
- keys in the subtree of $\boldsymbol{v}_{1}$ are less than $\boldsymbol{k}_{1}$
- keys in the subtree of $\boldsymbol{v}_{\boldsymbol{i}}$ are between $\boldsymbol{k}_{i-1}$ and $\boldsymbol{k}_{\boldsymbol{i}}(\boldsymbol{i}=2, \ldots, \boldsymbol{d}-1)$
- keys in the subtree of $\boldsymbol{v}_{d}$ are greater than $\boldsymbol{k}_{d-1}$
- The leaves store no items and serve as placeholders

## Multi-Way Searching

- Similar to search in a binary search tree
* A each internal node with children $\boldsymbol{v}_{1} \boldsymbol{v}_{2} \ldots \boldsymbol{v}_{d}$ and keys $\boldsymbol{k}_{1} \boldsymbol{k}_{2} \ldots \boldsymbol{k}_{d-1}$ - $\boldsymbol{k}=\boldsymbol{k}_{\boldsymbol{i}}(\boldsymbol{i}=1, \ldots, \boldsymbol{d}-1)$ : the search terminates successfully
- $\boldsymbol{k}<\boldsymbol{k}_{1}$ : we continue the search in child $\boldsymbol{v}_{1}$
- $\boldsymbol{k}_{i-1}<\boldsymbol{k}<\boldsymbol{k}_{\boldsymbol{i}}(\boldsymbol{i}=2, \ldots, \boldsymbol{d}-1)$ : we continue the search in child $v_{i}$
- $\boldsymbol{k}>\boldsymbol{k}_{d-1}$ : we continue the search in child $v_{d}$
- Reaching an external node terminates the search unsuccessfully
- Example: search for 30

## $(2,4)$ Trees (§ 9.4.2)

- A $(2,4)$ tree (also called 2-4 tree or 2-3-4 tree) is a multi-way search with the following properties
- Node-Size Property: every internal node has at most four children
- Depth Property: all the external nodes have the same depth
- Depending on the number of children, an internal node of a $(2,4)$ tree is called a 2 -node, 3 -node or 4 -node

## Height of a $(2,4)$ Tree

- Theorem: A $(2,4)$ tree storing $\boldsymbol{n}$ items has height $\boldsymbol{O}(\log \boldsymbol{n})$ Proof:
- Let $\boldsymbol{n}$ be the height of a $(2,4)$ tree with $n$ items
- Since there are at least $2^{i}$ items at depth $\boldsymbol{i}=0, \ldots, \boldsymbol{h}-1$ and no items at depth $h$, we have

$$
n \geq 1+2+4+\ldots+2^{h-1}=2^{h}-1
$$

- Thus, $\boldsymbol{h} \leq \log (\boldsymbol{n}+1)$
- Searching in a $(2,4)$ tree with $n$ items takes $\boldsymbol{O}(\log n)$ time depth items

## Insertion

- We insert a new item $(\boldsymbol{k}, \boldsymbol{o})$ at the parent $\boldsymbol{v}$ of the leaf reached by searching for $\boldsymbol{k}$
- We preserve the depth property but
- We may cause an overflow (i.e., node $v$ may become a 5 -node)
- Example: inserting key 30 causes an overflow

## Overflow and Split

- We handle an overflow at a 5-node $v$ with a split operation:
- let $\boldsymbol{v}_{1} \ldots \boldsymbol{v}_{5}$ be the children of $\boldsymbol{v}$ and $\boldsymbol{k}_{1} \ldots \boldsymbol{k}_{4}$ be the keys of $\boldsymbol{v}$
- node $v$ is replaced nodes $v^{\prime}$ and $v^{\prime \prime}$
- $\boldsymbol{v}^{\prime}$ is a 3 -node with keys $\boldsymbol{k}_{1} \boldsymbol{k}_{2}$ and children $\boldsymbol{v}_{1} v_{2} v_{3}$
- $v^{\prime \prime}$ is a 2 -node with key $k_{4}$ and children $v_{4} v_{5}$
- key $\boldsymbol{k}_{3}$ is inserted into the parent $\boldsymbol{u}$ of $\boldsymbol{v}$ (a new root may be created)
- The overflow may propagate to the parent node $u$

## Analysis of Insertion

## Algorithm insert $(k, o)$

1. We search for key $\boldsymbol{k}$ to locate the insertion node $\boldsymbol{v}$
2. We add the new entry $(\boldsymbol{k}, \boldsymbol{o})$ at node $\boldsymbol{v}$
3. while overflow(v)
if isRoot( $\nu$ )
create a new empty root above $v$ $v \leftarrow \operatorname{split}(v)$

- Let $T$ be a $(2,4)$ tree with $n$ items
- Tree $\boldsymbol{T}$ has $\boldsymbol{O}(\log \boldsymbol{n})$ height
- Step 1 takes $\boldsymbol{O}(\log n)$ time because we visit $O(\log \boldsymbol{n})$ nodes
- Step 2 takes $\boldsymbol{O}(1)$ time
- Step 3 takes $\boldsymbol{O}(\log \boldsymbol{n})$ time because each split takes $\boldsymbol{O}(1)$ time and we perform $\boldsymbol{O}(\log n)$ splits
- Thus, an insertion in a $(2,4)$ tree takes $\boldsymbol{O}(\log \boldsymbol{n})$ time

## Deletion

- We reduce deletion of an entry to the case where the item is at the node with leaf children
- Otherwise, we replace the entry with its inorder successor (or, equivalently, with its inorder predecessor) and delete the latter entry
- Example: to delete key 24, we replace it with 27 (inorder successor)

(c) 2004 Goodrich, Tamassia
$(2,4)$ Trees

## Underflow and Fusion

- Deleting an entry from a node $v$ may cause an underflow, where node $v$ becomes a 1-node with one child and no keys
- To handle an underflow at node $v$ with parent $u$, we consider two cases
- Case 1: the adjacent siblings of $v$ are 2-nodes
- Fusion operation: we merge $v$ with an adjacent sibling $w$ and move an entry from $\boldsymbol{u}$ to the merged node $\boldsymbol{v}^{\prime}$
- After a fusion, the underflow may propagate to the parent $u$

## Underflow and Transfer

- To handle an underflow at node $v$ with parent $\boldsymbol{u}$, we consider two cases
- Case 2: an adjacent sibling $w$ of $v$ is a 3-node or a 4-node
- Transfer operation:

1. we move a child of $w$ to $v$
2. we move an item from $u$ to $v$
3. we move an item from $w$ to $u$

- After a transfer, no underflow occurs

## Analysis of Deletion

* Let $T$ be a $(2,4)$ tree with $n$ items
- Tree $\boldsymbol{T}$ has $\boldsymbol{O}(\log \boldsymbol{n})$ height
$*$ In a deletion operation
- We visit $\boldsymbol{O}(\log \boldsymbol{n})$ nodes to locate the node from which to delete the entry
- We handle an underflow with a series of $\boldsymbol{O}(\log \boldsymbol{n})$ fusions, followed by at most one transfer
- Each fusion and transfer takes $\boldsymbol{O}(1)$ time
*Thus, deleting an item from a $(2,4)$ tree takes $\boldsymbol{O}(\log \boldsymbol{n})$ time

## Implementing a Dictionary

- Comparison of efficient dictionary implementations

|  | Search | Insert | Delete | Notes |
| :---: | :---: | :---: | :---: | :--- |
